Seminar 4

1. A confusion matrix is an N dimensional square matrix, where N represents total number of target classes or categories. There are four important terms in a confusion matrix: TP, TN, FP, FN. Explain these terms.

| | Predicted: NO | Predicted: YES |
|-------------|---------------------|---------------------|
| Actual: NO | True Negative (TN) | False Positive (FP) |
| Actual: YES | False Negative (FN) | True Positive (TP) |

2. For the confusion matrix below, calculate the sensitivity, specificity, positive predictive value, negative predictive value and accuracy.

| Confusion Matrix | | Target | |
|------------------|----------|----------|----------|
| | | Positive | Negative |
| Model | Positive | 70 | 20 |
| | Negative | 30 | 80 |

3. Below is a confusion matrix for a multi-class dataset. Convert it into a one-vs-all type matrix (binary-class confusion matrix).

| | | Expected | | | |
|-----------|---|----------|----|----|----|
| | | 1 | 2 | 3 | 4 |
| Predicted | 1 | 52 | 3 | 7 | 2 |
| | 2 | 2 | 28 | 2 | 0 |
| | 3 | 5 | 2 | 25 | 12 |
| | 4 | 1 | 1 | 9 | 40 |

4. For the binary-class confusion matrix you derived in Q3, calculate the precision, recall and F1-score.

5. Hold-out cross-validation is the simplest and most common technique. You might not know that it is a hold-out method, but you certainly use it every day.

The algorithm of hold-out technique:

- Divide the dataset into two parts: the training set and the test set. Usually, 80% of the dataset goes to the training set and 20% to the test set but you may choose any splitting that suits you better
- Train the model on the training set
- Validate on the test set
- Save the result of the validation

What is the limitation of this result? Can you think of other better validation methods?
